# Optimization Methods in Management Science MIT 15.053, Spring 2013 PROBLEM SET 2 (FIRST GROUP OF STUDENTS) Students with first letter of surnames A–H DUE: FEBRUARY 21, 2013

#### **Problem Set Rules:**

- 1. Each student should hand in an individual problem set.
- 2. Discussing problem sets with other students is permitted. Copying from another person or solution set is *not* permitted.
- 3. Late assignments will *not* be accepted. No exceptions.
- 4. The non-Excel solution should be handed in at the beginning of class on the day the problem set is due. The Excel solutions, if required, should be posted on the website by the beginning of class on the day the problem set is due. Questions that require an Excel submission are marked with <u>EXCEL SUBMISSION</u>. For <u>EXCEL SUBMISSION</u> questions, only the Excel spreadsheet will be graded.

### Problem 1

(33 points total) Consider the following linear program:

$$\begin{array}{cccc} \max & x_1 + 2x_2 & & \\ \text{s.t.:} & & & \\ \text{Const 1} & x_1 - x_2 & \geq & -2 \\ \text{Const 2} & x_1 + x_2 & \leq & 4 \\ \text{Const 3} & x_1 & \leq & 2.5 \\ \text{Const 4} & x_2 & \leq & 3 \\ & & x_1, x_2 & \geq & 0. \end{array} \right\}$$
(LP)

- (a) (5 points) Graph the feasible region of the LP. Is the feasible region unbounded?
- (b) (4 points) Are any of the above constraints redundant? If so, indicate which one(s). (For large linear programs, eliminating redundant constraints can speed up the solution of the linear program.)
- (c) (4 points) Solve the LP using the graphical method. Explain your approach.
- (d) (4 points) Is there more then one optimal solution? If so give two different solutions. If not, explain using the graphical method why not?
- (e) (9 points, 3 points each) Suppose we add the constraint  $2x_1 + x_2 \ge \alpha$  to (LP). For which values of  $\alpha$ :
  - is the constraint redundant?

- the optimal solution found above is no longer optimal?
- the problem becomes infeasible?

To answer these questions, you should use the graph of the feasible region drawn in Part (a).

(f) (4 points) Replace the objective function  $x_1 + 2x_2$  with the objective function  $x_1 + \beta x_2$ , and compute the values of  $\beta$  for which the point (2.5, 1.5) is optimal.

## Problem 2<sup>1</sup>

(38 points total) A company makes three lines of tires. Its four-ply biased tires produce \$6 in profit per tire; its fiberglass belted line \$4 a tire; and its radials \$8 a tire. Each type of tire passes through three manufacturing stages as a part of the entire production process.

Each of the three process centers has the following hours of available production time per day:

	Process	Hours
1	Modeling	12
2	Curing	14
3	Assembly	16

The time required in each process to produce one hundred tires of each line is as follows:

	Hours per 100 units		
Tire	Modeling	Curing	Assembly
Four-ply	2	3	2
Fiberglass	2	2	1
Radial	4	2	2

- (a) (5 points) Write a linear program to determine the optimum product mix for each day's production, assuming all tires are sold.
- (b) (10 points) <u>EXCEL SUBMISSION</u> Solve the problem using the simplex algorithm, employing the Excel spreadsheet given with this problem set. Make sure you understand the formulation and the meaning of the variables, and fill in the missing coefficients of the tableau. The spreadsheet that you submit should contain the sequence of tableaus that leads to the optimal tableau *only*. You will then use the same spreadsheet to help through the rest of Problem 2, but make sure you submit a spreadsheet containing the sequence of tableaus leading to the optimal tableau for the *original* data!
- (c) (8 points) Using the Excel spreadsheet to carry out the calculations, answer the following question:
  - (1) What is the initial feasible solution? Give the value for all the decision variables and all the slack variables.
  - (2) What is the optimal solution? Give its objective function value and the value of all the decision variables.

<sup>&</sup>lt;sup>1</sup>This problem is based on Problem 6 of Applied Mathematical Programming, Chapter 2.

- (d) (15 points, 5 points each) Using the Excel spreadsheet from the previous point to recompute the optimal solution of the LP, answer the following questions:
  - (i) Suppose we increase the number of modeling hours per day from 12 to 13. How much does the profit increase? (Comment: This is the *shadow price* of the constraint on the modeling hours. Read the tutorial on "Sensitivity Analysis in 2 Dimensions" to learn more about shadow prices.)
  - (ii) What would be the increase in the profit if we increase the number of assembly hours per day from 16 to 17 (Assume that the number of modeling hours per day is 12.)
  - (iii) (Extra credit) Consider the answer to the previous two questions. What relationship do you observe between the shadow price of a constraint and the value of the corresponding slack variable in the optimal solution?

### Problem 3 (First group of students)<sup>2</sup>

(34 points total) Charles Watts Electronics manufactures the following six peripheral devices used in computers specially designed for jet fighter planes: internal modems, external modems, graphics circuit boards, USB memory stick, hard disk drives, and memory expansion boards. Each of these technical products requires time, in minutes, on three types of electronic testing equipment as shown in the following table:

	Internal	External	Circuit	USB	Hard	Memory
	Modem	Modem	Board	$\mathbf{Stick}$	Drives	Boards
Test device 1	7	3	12	6	18	17
Test device 2	2	5	3	2	15	17
Test device 3	5	1	3	2	9	2

The first two test devices are available 130 hours per week. The third (device 3) requires more preventive maintenance and may be used only 100 hours each week. Watts Electronics believes that it cannot sell more than 2000, 1500, 1800, 1200, 1000, 1000 units of each device, respectively. Thus, it does not want to produce more than these units. The table that follows summarizes the revenues and material costs for each product:

	Revenue per	Material Cost
Device	unit sold (\$)	per unit (\$)
Internal modem	200	35
External modem	120	25
Circuit board	180	40
USB memory stick	130	45
Hard disk drive	430	170
Memory expansion board	260	60

In addition, variable labor costs are \$16 per hour for test device 1, \$12 per hour for test device 2, and \$18 per hour for test device 3. Watts Electronics wants to maximize its profits. This

<sup>&</sup>lt;sup>2</sup>This problem is based on Problem B.29 of Operations Management by Heizer and Render (2010).

problem can be formulated as follows:

max	$x_I \Big( 200 - 35 - (7/60)16 - (2/60)12 - (5/60)18 \Big) +$		
	$x_E \left( 120 - 25 - (3/60)16 - (5/60)12 - (1/60)18 \right) +$		
	$x_C(180 - 40 - (12/60)16 - (3/60)12 - (3/60)18) +$		
	$x_U (130 - 45 - (6/60)16 - (2/60)12 - (2/60)18) +$		
	$x_H(430 - 170 - (18/60)16 - (15/60)12 - (9/60)18) +$		
	$x_M (260 - 60 - (17/60)16 - (17/60)12 - (2/60)18)$		
s.t.:			
Availability Test Dev. 1:	$7x_I + 3x_E + 12x_C + 6x_U + 18x_H + 17x_M$	$\leq$	130 * 60
Availability Test Dev. 2 :	$2x_I + 5x_E + 3x_C + 2x_U + 15x_H + 17x_M$	$\leq$	130 * 60
Availability Test Dev. 3 :	$5x_I + 1x_E + 3x_C + 2x_U + 9x_H + 2x_M$	$\leq$	100 * 60
Max int modem demand :	$x_I$	$\leq$	2000
Max ext modem demand $:$	$x_E$	$\leq$	1500
Max circuit demand :	$x_C$	$\leq$	1800
Max USB memory demand :	$x_U$	$\leq$	1200
Max hard disk demand $:$	$x_H$	$\leq$	1000
Max memory demand :	$x_M$	$\leq$	1000
	$x_I, x_E, x_C, x_U, x_H, x_M$	$\geq$	0.

In this problem, there are six decision variables that indicate the number of devices as:

$x_I =$	the number of internal modems	$x_E =$ the number of external modems
$x_C =$	the number of circuit boards	$x_U =$ the number of USB memory sticks
$x_H =$	the number of hard disk drives	$x_M =$ the number of memory expansion boards

You are given an Excel spreadsheet that solves the above problem. Suppose that the labor costs are changed to \$18 per hour for test device 1, \$15 per hour for test device 2, and \$12 per hour for test device 3. In addition, Watts Electronics considers producing external hard drives, with \$127 of revenue per unit, and \$50 of the material cost per unit. All external hard drives will be sold. The required time, in minutes, on the three testing devices are given as follows:

	External hard drives
Test device 1	3
Test device 2	2
Test device 3	6

All other data remains unchanged. Update the Excel spreadsheet and answer the following questions:

- (a) (10 points) What is the optimal profit and the optimal production-mix?
- (b) (5 points) As you see from the solution in Part (a), no external hard drives is produced in the optimal production-mix. What is the minimum increase in the revenue of external hard drive (in terms of \$ per unit), before they will be included in the optimal production mix? (Be accurate within one dollar.)

- (c) (6 points) Suppose that Watts Electronics is considering increasing the available time of test device 2 for the next week. What would be the increase in the profit over the solution in Part (a) if the available time increases to 130 + t for t = 1, 2, and 3. (Assume that there are still 130 hours of test device 1 and 100 hours of test device 3.)
- (d) (8 points) Based on your answer in Part (c), estimate the optimal profit if the availability time of test device 2 increases to 140. (Use Excel solver to check if your estimate is correct.) What is the formula for the optimum profit if the availability time increased by 130 + t? (You may assume that t is between 1 and 10).
- (e) (5 points) Based on your formula in part (d), what is the contribution (the increase in optimal profit) if the availability time of test device 2 increases to 150. Use Excel solver to see if your estimation is correct (it won't). Use Excel solver to determine the maximum value of t for which your formula is correct (Be accurate to within an hour).
